

## Lecture 2: Sorting Algorithms

Throughout this lecture, we'll assume a ~~an~~ totally ordered type  $K$  of keys.

Sorting takes lists to lists.

We represent the input as data, but the output as co-data:

$\text{sort} :: \text{List } K \rightarrow \text{CoList } K$

One obvious structure is a fold:

$\text{isort} = \text{fold insert}$

$\text{insert} :: \text{List } K \rightarrow \text{CoList } K \rightarrow \text{CoList } K$

The obvious next step is an unfold:

$\text{insert} = \text{unfold ins}$

$\text{ins} :: \text{List } K \rightarrow \text{CoList } K \rightarrow \text{List } K \rightarrow \text{CoList } K$

It's not too difficult to complete the defn:

$\text{ins NilF} = \text{NilF}$

$\text{ins (ConsF a (Out NilF))} = \text{ConsF a NilF}$

$\text{ins (ConsF a (Out (ConsF b x)))}$

$\quad | a \leq b = \text{ConsF a (ConsF b x)}$

$\quad | a > b = \text{ConsF b (ConsF a x)}$

This definition is a bit clumsy, because it keeps recursing even after finding the right place to insert — we'll come back to that.

Another obvious place to start is on the structure of the output:

$\text{bSort} = \text{unfold bubble}$

$\text{bubble} :: \text{List } K \rightarrow \text{ListF } K (\text{List } K)$

Again, the next step is obvious:

$\text{bubble} = \text{fold bub}$

$\text{bub} :: \text{ListF } K (\text{ListF } K (\text{List } K)) \rightarrow \text{ListF } K (\text{List } K)$

And again, it's not too difficult to complete the definition:

$\text{bub NilF} = \text{NilF}$

$\text{bub (ConsF a NilF)} = \text{ConsF a (In NilF)}$

$\text{bub (ConsF a (ConsF b x))}$

$\quad | a \leq b = \text{ConsF a (In (ConsF b x))}$

$\quad | a > b = \text{ConsF b (In (ConsF a x))}$

Note that this is bubble sort, not the selection sort you might expect: at each step, the least element is extracted as the next element of the output, but the remaining elements get rearranged - we'll come back to this too.

In fact, these two sorting algorithms are very closely related: one is a fold whose body is an unfold, the other is an unfold with body a fold and the inner bodies are identical apart from isomorphisms  $\text{Out}^\circ$  and  $\text{In}$ .

If we define

$$\text{swap} :: \text{ListF } K (\text{ListF } K \alpha) \rightarrow \text{ListF } K (\text{ListF } K \alpha)$$

$$\text{swap NilF} = \text{NilF}$$

$$\text{swap} (\text{ConsF } a \text{ NilF}) = \text{ConsF } a \text{ NilF}$$

$$\text{swap} (\text{ConsF } a (\text{ConsF } b \ x))$$

$$| a \leq b = \text{ConsF } a (\text{ConsF } b \ x)$$

$$| a > b = \text{ConsF } b (\text{ConsF } a \ x)$$

then

$$\text{ins} = \text{swap} \cdot \text{bimap id out}$$

$$\text{bub} = \text{bimap id In} \cdot \text{swap}$$

(Note that their earlier types are over-specific: they are both parameters in argument  $\alpha$ .) Hinze et al (WGP 2012) explain that  $(\text{ConsF } K, \text{insert}, \text{out})$  and  $(\text{ListF } K, \text{In}, \text{bubble})$  are both  $(\text{ListF } K)$ -bialgebras for distributive law  $\text{swap}$ .

The close correspondence between (naive) insertion sort and bubble sort can also be seen pictorially.

Sorting networks can be built from  $2 \times 2$

comparators. A column of these computes the minimum of a collection; a row inserts into a sorted sequence.

Then a triangular array of comparators forms a sorting network, and can be viewed as either a stack of inserters or a pipeline of selectors. (Thanks to MFL, Ruby, Lava.)

Recall bubbleSort. To get selection sort instead, we need to select the minimum at each stage, but leave the remainder in same order.

So when head is minimum, we should return tail unchanged. We have to preserve this tail to do so.

fold :: Bifunctor f => (f x beta -> beta) -> Mufx -> fold q = q . bimap id (fold q) . in<sup>o</sup>

Generalize to paramorphism:

para :: Bifunctor f => (f x (beta x Mufx) -> beta) -> Mufx -> para q = q . bimap id (~~fold~~<sup>para</sup> q & id) . in<sup>o</sup>

At each substructure, we make avail at both the original structure and its image under the computation. Then

ssort = fold select

select = para sel

sel :: ListF k (ListF k (List k) x List k) -> ListF k (List k (ListF k (List k) x List k))

| a <= b = ComF a y

| a > b = ComF b (In (ComF a x))

(other cases as for bub).

Dually, to get a smarter insertion sort, we should stop inserting when the right position is found - we need a way to leap straight to result.

unfold :: Bifunctor f => (beta -> f alpha beta) -> beta -> Mu f alpha  
 unfold phi = Out<sup>o</sup> . bimap id (unfold phi) . phi

Generalize to apomorphism:

apo :: Bifunctor f => (beta -> f alpha (beta + Nu f alpha)) -> beta -> Nu f alpha  
 apo phi = Out<sup>o</sup> . bimap id (apo phi v id) . phi

For each substructure, we either get a seed for a corecursive call, or the result.

insert = apo smartins

smartins :: List f K (CoList K) ->  
 List f K (List f K (CoList K) + CoList K)

smartins (Cons f a (Out<sup>o</sup> (Cons f b x)))

| a <= b = Cons f a (Right (Out<sup>o</sup> (Cons f b x)))

| a > b = Cons f b (Left (Cons f a x))

smartins (Cons f a (Out<sup>o</sup> Nil f))

= Cons f a (Left Nil f)

or = Cons f a (Right (Out<sup>o</sup> Nil f))

smartins Nil f = Nil f
